Today I have learned about competences and the five major competences an Engineer for Sustainability should have in their tool box namely: Technical competence, methodological competence, Sustainability competence and lastly social and personal competence. The current rant i'm writing ~~builds up~~ is aimed at at improving and building on my personal competences.

Another important aspect i've learned today is the distinction between knowledge and Competence as knowledge is what I know and competence the ability to apply that knowledge in order to achieve a goal. Competences first and knowledge second meaning learn how to apply what you know over simply reproducing it.

Lastly I will also like to point out a shift in mentality in me which is thinking about sustainability everywhere and putting sustainability first. ~~Not being too tunnel visioned into simply resolving the problem~~ Essentially not being too tunnel visionned into resolving a problem and thinking of financial benefits but taking into consideration long term effects at the environmental, and social level.

* Risk = Consequence × Likelihood *

Risk is ~~Deter~~ determined by combining the likelihood of an event occurring with the severity of the consequence. ~~This can also be~~

Risk can be assessed using the table below.

Risk	Likelihood	Consequence	Technical solution	Behavioral solution	Procedu solution

Fig: The table above is a table of Risk assessment. Various Potential risk are written under the "Risk" Column. The likelihood of it happening on a scale from 1-10 under likelihood, Potential consequences that could arise under the heading "Consequences". Potential ~~technical~~ solutions, ~~Both~~ be it Behavioral, Technical or procedural under their respective headings.
